A longstanding open problem in lambda calculus is whether there exist continuous models of the untyped lambda calculus whose theory is exactly the $\lambda\beta$ or the least sensible lambda-theory \mathcal{H} (generated by equating all the unsolvable terms). A related question is whether, given a class of lambda models, there is a minimal lambda-theory represented by it. In this paper, we give a general tool to answer positively to this question and we apply it to a wide class of webbed models: the i-models. The method then applies also to graph models, Krivine models, coherent models and filter models. In particular, we build an i-model whose theory is the set of equations satisfied in all i-models.

1 Introduction

Lambda-theories are congruences on the set of λ -terms which contain β -conversion, providing (sound) notions of program equivalence. Models of the λ -calculus are one of the main tools used to study the lattice of λ -theories. Some of them, called webbed models, are built from lower level structures called “webs” (see Berline [6] for an extensive survey). The simplest class of webbed models is the class of graph models, which was isolated in the seventies by Plotkin, Scott and Engeler [15, 21, 23] within the continuous semantics. The class of graph models contains the simplest models of λ -calculus, is itself the easiest describable class, and represents nevertheless a continuum of (non-extensional) lambda-theories. Another example of a class of webbed models, and the most established one, is the class of filter models. It was isolated at the beginning of the eighties by Barendregt, Coppo and Dezani [4], after the introduction of the intersection type discipline by Coppo and Dezani [12]. Not all filter models live in Scott continuous semantics: for example some of them lack the property of representing all continuous functions, and others were introduced for the stable semantics (see Honsell–Ronchi [16], Bastonero et al. [5]).

In general, given a class \mathcal{C} of models, a natural completeness problem arises for it: whether the class is *complete*, i.e., for any lambda-theory T there exists a member of \mathcal{C} whose equational theory is T . A related question, raised in [6] is the following: given a class \mathcal{C} of models of the λ -calculus, is there a minimal lambda-theory represented by \mathcal{C} ? If this is the case, we say that \mathcal{C} enjoys the *minimality property*. In [14] it was shown that the above question admits a positive answer for Scott’s continuous semantics, at least if we restrict to extensional relexive CPO-models. Another result, in the same spirit, is the construction of a model whose theory is $\lambda\beta\eta$, *a fortiori* minimal, in the ω_1 -semantics. However, the proofs of [14] use logical relations, and since logical relations do not allow to distinguish terms with the same applicative behavior, the proofs do not carry out to non-extensional models. Similarly, in [9], it is shown that the class of graph models enjoys the minimality property.

In this paper, we propose a method to prove that a given class of models enjoys the minimality property, based on two main ingredients: the *finite intersection property* (fip) and the *ultraproduct property* (upp). The finite intersection property is satisfied by a class \mathcal{C} of models if for all models $\mathbf{M}_1, \mathbf{M}_2$ in \mathcal{C} there exists a model \mathbf{M} in \mathcal{C} whose theory is included in $Th(\mathbf{M}_1) \cap Th(\mathbf{M}_2)$. The ultraproduct property is

satisfied in \mathcal{C} if for every non-empty family $\{\mathbf{M}_i\}_{i \in I}$ of members of \mathcal{C} and for every proper ultrafilter U of sets on $\mathcal{P}(I)$ the ultraproduct $(\prod_{i \in I} \mathbf{M}_i)/U$ can be embedded into a member of \mathcal{C} . We show in Theorem 3.1 that if these conditions are satisfied, then \mathcal{C} has the minimality property. An important technical device used in the proof of Theorem 3.1 is Löb's Theorem: the ultraproduct of a family of models satisfies an (in)equation between λ -terms if and only if the set of indexes of the component models satisfying it belongs to the ultrafilter. Hence, proving the minimality property boils down to exhibiting an appropriate ultrafilter.

As an application of this general method, we prove that the class of i-models introduced in [10] enjoys the minimality property. First of all, for every pair of i-models \mathbf{A}, \mathbf{B} we construct an i-model \mathbf{C} such that $Th(\mathbf{C}) \subseteq Th(\mathbf{A}) \cap Th(\mathbf{B})$. This result is obtained via a sophisticated completion process applied to the categorical product of \mathbf{A} and \mathbf{B} , adapted from [10]. In order to prove that the class of i-models enjoys the ultraproduct property, we exploit the fact that i-models are webbed models. Given an ultraproduct of i-models, P , we construct the ultraproduct of the corresponding webs, P' , which turns out to be a well defined web, and show that there exists an embedding of combinatory algebra from P to the i-model associated to P' . We also show how our proof applies to smaller classes of webbed models, like graph models, Krivine models, coherent models, and filter models.

The paper is organized as follows. In Section 2 we provide the preliminary notions and results needed in the rest of the paper, in section 3 we present the general method for showing that a given class of models of the λ -calculus has the minimality property, and a couple of interesting corollaries of upp, and in section 4 we apply this method to the class of the i-models.

2 Preliminaries

2.1 Lambda-theories and models of λ -calculus

With regard to the λ -calculus we follow the notation and terminology of [3]. By Λ and Λ° , respectively, we indicate the set of λ -terms and of closed λ -terms. We denote $\alpha\beta$ -conversion by $\lambda\beta$. A λ -theory is a congruence on Λ (with respect to the operators of abstraction and application) which contains $\lambda\beta$. A lambda-theory is *consistent* if it does not equate all λ -terms, *inconsistent* otherwise. The set of lambda-theories constitutes a complete lattice w.r.t. inclusion, whose top is the inconsistent lambda-theory and whose bottom is the theory $\lambda\beta$. The lambda-theory generated by a set X of identities is the intersection of all lambda-theories containing X .

It took some time, after Scott gave his model construction, for consensus to arise on the general notion of a model of the λ -calculus. There are mainly two descriptions that one can give: the category-theoretical and the algebraic one. Besides the different languages in which they are formulated, the two approaches are intimately connected (see Koymans [18]). The categorical notion of model is well-suited for constructing concrete models, while the algebraic one is rather used to understand global properties of models (constructions of new models out of existing ones, closure properties, etc.) and to obtain results about the structure of the lattice of lambda-theories.

2.2 Ultraproducts of λ -models

Reduced products result from a certain combination of the direct product and quotient constructions. They were introduced in the 1950's by Łoś and the special case of ultraproducts has been a subject worthy of at least one book.

Let I be a non-empty set and let $\{\mathbf{A}_i\}_{i \in I}$ be a family of combinatory algebras. Let U be a proper ultrafilter of the boolean algebra $\mathcal{P}(I)$ and define a relation \sim_U given by $a \sim_U b \Leftrightarrow \{i \in I : a(i) = b(i)\} \in U$. Then θ is a congruence on the combinatory algebra $\prod_{i \in I} \mathbf{A}_i$. The *ultraproduct* of the family $\{\mathbf{A}_i\}_{i \in I}$, noted $(\prod_{i \in I} \mathbf{A}_i)/U$ is defined as the quotient of the product $\prod_{i \in I} \mathbf{A}_i$ by the congruence \sim_U . Now if all members of $\{\mathbf{A}_i\}_{i \in I}$ are λ -models, by a celebrated theorem of Łoś we have that $(\prod_{i \in I} \mathbf{A}_i)/U$ is a λ -model too, because λ -models are axiomatized by first-order sentences. The basic combinators of the λ -model $(\prod_{i \in I} \mathbf{A}_i)/U$ are $\mathbf{k}^{\prod_{i \in I} \mathbf{A}_i}/U$ and $\mathbf{s}^{\prod_{i \in I} \mathbf{A}_i}/U$ and application is given by $x/U \cdot y/U = (x \cdot y)/U$, where the application $x \cdot y$ is defined pointwise.

We now recall the famous theorem Łoś that we will use throughout this paper.

Theorem 2.1 (Łoś). *Let $\{\mathbf{A}_i\}_{i \in I}$ be a family of first-order structures indexed by a non-empty set I and let U be a proper ultrafilter of $\mathcal{P}(I)$. Then for every first-order \mathcal{L} -formula $\varphi(x_1, \dots, x_n)$ and for every tuple $(a_1, \dots, a_n) \in \prod_{i \in I} \mathbf{A}_i$ we have that*

$$(\prod_{i \in I} \mathbf{A}_i)/U \models \varphi(a_1/U, \dots, a_n/U) \Leftrightarrow \{i \in I : \mathbf{A}_i \models \varphi(a_1(i), \dots, a_n(i))\} \in U$$

2.3 Information systems

Information systems were introduced by Dana Scott in [22] to give a handy representation of Scott domains. An *information system* is a tuple $\mathcal{A} = (A, \text{Con}_A, \vdash_A, v_A)$, where A is a set and $v_A \in A$, $\text{Con}_A \subseteq \mathcal{P}_f(A)$ is a downward closed family containing all singleton subsets of A , and $\vdash_A \subseteq \text{Con}_A \times A$ satisfies the four axioms listed below:

- (I1) if $a \in \text{Con}_A$ and $a \vdash_A b$, then $a \cup b \in \text{Con}_A$ (where $a \vdash_A b \stackrel{\text{def}}{=} \forall \beta \in b. a \vdash_A \beta$)
- (I2) if $\alpha \in a$, then $a \vdash_A \alpha$
- (I3) if $a \vdash_A b$ and $b \vdash_A \gamma$, then $a \vdash_A \gamma$
- (I4) $\emptyset \vdash_A v_A$

We adopt the following notational conventions: letters $\alpha, \beta, \gamma, \dots$ are used for elements of A (also called *tokens*); letters a, b, c, \dots are used for elements of Con_A , usually called *consistent sets*; letters x, y, z, \dots are used for arbitrary elements of $\mathcal{P}(A)$. We usually drop the subscripts from Con_A and \vdash_A when there is no danger of confusion.

Scott proposed information systems as structures where the “backbone” of a domain is introduced by just a few axioms. Then the domain itself is defined as a certain construction from the backbone in order to define the appropriate notion of element. Scott’s idea was not only to offer a simple alternative to domains, but also to continuous functions: in fact his purpose was to describe at a “lower lever” the entire category **SD**. For this reason he also defined an appropriate notion of morphism between information systems.

An *approximable relation* between two information systems \mathcal{A}, \mathcal{B} is a relation $R \subseteq \text{Con}_A \times B$ satisfying the following properties:

- (AR1) if $a \in \text{Con}_A$ and $a R b$, then $b \in \text{Con}_B$ (where $a R b \stackrel{\text{def}}{=} \forall \beta \in b. a R \beta$)
- (AR2) if $a' \vdash_A a$, $a R b$, and $b \vdash_B \beta'$, then $a' R \beta'$

We will call **Inf** the category which has information systems as objects and approximable relations as arrows. The composition of two morphisms $R \in \mathbf{Inf}(\mathcal{A}, \mathcal{B})$ and $S \in \mathbf{Inf}(\mathcal{B}, \mathcal{C})$ is (using the meta-notation) their usual relational composition: $S \circ R = \{(a, \gamma) \in \text{Con}_A \times C : \exists b \in \text{Con}_B. (a, b) \in R \text{ and } (b, \gamma) \in S\}$. The identity morphism of an information system \mathcal{A} is \vdash_A .

The ccc structure of **Inf** is described in [22], and we recall it here for the sake of self-containment.

In what follows we use the projection functions fst and snd of a set-theoretic Cartesian product over the first and second component, respectively.

Definition 2.1. *The Cartesian product of \mathcal{A} and \mathcal{B} is given by $\mathcal{A} \& \mathcal{B} = (A \uplus B, \text{Con}, \vdash, \nu)$ where*

$$\begin{aligned} A \uplus B &= (\{v_A\} \times B) \cup (A \times \{v_B\}) & \nu &= (v_A, v_B) \\ a \in \text{Con} &\text{ iff } \text{fst}^*(a) \in \text{Con}_A \text{ and } \text{snd}^*(a) \in \text{Con}_B \\ a \vdash \alpha &\text{ iff } \text{fst}^*(a) \vdash_A \text{fst}(\alpha) \text{ and } \text{snd}^*(a) \vdash_B \text{snd}(\alpha) \end{aligned}$$

The terminal object is the information system \top whose underlying set contains only one token.

Definition 2.2. *The exponentiation of \mathcal{B} to \mathcal{A} is given by $\mathcal{A} \Rightarrow \mathcal{B} = (A \Rightarrow B, \text{Con}, \vdash, \nu)$ where*

$$\begin{aligned} A \Rightarrow B &= \text{Con}_A \times B & \nu &= (\emptyset, v_B) \\ \{(a_1, \beta_1), \dots, (a_k, \beta_k)\} \in \text{Con} &\text{ iff } \forall I \subseteq [1, k]. (\cup_{i \in I} a_i \in \text{Con}_A \Rightarrow \{\beta_i : i \in I\} \in \text{Con}_B) \\ \{(a_1, \beta_1), \dots, (a_k, \beta_k)\} \vdash (c, \gamma) &\text{ iff } \{\beta_i : c \vdash_A a_i, i \in [1, k]\} \vdash_B \gamma \end{aligned}$$

The categories **SD** and **Inf** are isomorphic, via a pair of mutually inverse ccc-functors $(\cdot)^+ : \mathbf{Inf} \rightarrow \mathbf{SD}$ and $(\cdot)^- : \mathbf{SD} \rightarrow \mathbf{Inf}$. In particular for an information system \mathcal{A} , we have that $\mathcal{A}^+ = \mathbf{Inf}(\top, \mathcal{A})$, i.e., the set of points of an information system, ordered by inclusion, is a Scott domain. Moreover the domains $[\mathcal{A}^+ \rightarrow \mathcal{B}^+]$ and $\mathcal{A}^+ \times \mathcal{B}^+$ are isomorphic (in the category **SD**) to the domains $(\mathcal{A} \Rightarrow \mathcal{B})^+$ and $(\mathcal{A} \& \mathcal{B})^+$, respectively.

2.4 Webbed models of λ -calculus

Some of the models of λ -calculus are called *webbed models* because they are built from lower level structures called “webs” (see Berline [6, 7] for an accurate survey). Typically a web is a set with additional structure and a webbed model is a partial order (usually a domain) whose elements are special subsets of the web. We now introduce a class of webbed models of λ -calculus arising from information systems that include many others, among which the filter models of λ -calculus living in **CPO**.

Let \mathcal{A} be an information system. A subset $x \subseteq A$ is *finitely consistent* if each of its finite subsets belongs to Con_A . We define a partial operator $(\cdot) \downarrow_A : \mathcal{P}(A) \rightarrow \mathcal{P}(A)$ by setting $x \downarrow_A = \{\alpha \in A : \exists a \subseteq_f x. a \vdash \alpha\}$ if x is finitely consistent and undefined otherwise. We may drop the subscript when the underlying information system is clear from the context. Note that $(\cdot) \downarrow$ is a monotone map satisfying the following conditions: $x \subseteq x \downarrow$, $x \downarrow \downarrow = x \downarrow$ and $x \downarrow = \cup_{a \subseteq_f x} a \downarrow$.

Up to a trivial isomorphism, $\mathcal{A}^+ = \mathbf{Inf}(\top, \mathcal{A})$ is the set finitely consistent subsets $x \subseteq A$ such that $x = x \downarrow$. Therefore use the word point to denote these latter subsets.

Let \mathcal{A}, \mathcal{B} be information systems and let $f : A \rightarrow B$ be a function. We define two Scott continuous functions $f^\bullet : \mathcal{A}^+ \rightarrow \mathcal{B}^+$ and $f_\bullet : \mathcal{B}^+ \rightarrow \mathcal{A}^+$ as follows:

$$f^\bullet(x) = \{f(\alpha) : \alpha \in x\} \downarrow_B ; \quad f_\bullet(y) = \{\alpha : f(\alpha) \in y\} \downarrow_A$$

for every point x of \mathcal{A} and every point y of \mathcal{B} . We want to give simple conditions under which f can generate a continuous retraction from \mathcal{A}^+ to \mathcal{B}^+ : these conditions were introduced in [10].

Definition 2.3 ([10]). *Let \mathcal{A}, \mathcal{B} be information systems. A morphism from \mathcal{A} to \mathcal{B} is a function $f : A \rightarrow B$ satisfying the following property:*

$$(Mo) \quad a \in \text{Con}_A \text{ iff } f^*(a) \in \text{Con}_B$$

Definition 2.4 ([10]). A morphism $f : \mathcal{A} \rightarrow \mathcal{B}$ is a *b-morphism* (resp. *f-morphism*) if it satisfies the following property (*bMo*) (resp. (*fMo*))

$$\begin{aligned} (bMo) \quad & \text{if } f^*(a) \vdash_B f(\alpha), \text{ then } a \vdash_A \alpha \\ (fMo) \quad & \text{if } a \vdash_A \alpha, \text{ then } f^*(a) \vdash_B f(\alpha) \end{aligned}$$

The “b” (resp. “f”) in the name of the axiom stands for backward (resp. forward). We leave to the reader the easy relativization of the various notions of morphism given in Definition 2.4 to the case in which f is a partial map.

Proposition 2.2. Let $f : \mathcal{A} \rightarrow \mathcal{B}$ be a *b-morphism*. Then (f_\bullet, f^\bullet) is a retraction pair from \mathcal{A}^+ into \mathcal{B}^+ .

Proof. From (bMo) it follows $f_\bullet \circ f^\bullet = \text{id}_{\mathcal{A}^+}$. □

Definition 2.5. An *i-web* is a pair $\mathbf{A} = (\mathcal{A}, \phi_A)$ where \mathcal{A} is an information system and $\phi_A : \mathcal{A} \Rightarrow \mathcal{A} \rightarrow \mathcal{A}$ is a *b-morphism*.

The set of tokens of \mathcal{A} is called the *web* of \mathbf{A} .

Proposition 2.3. Let $\mathbf{A} = (\mathcal{A}, \phi_A)$ be an *i-web*. Then \mathcal{A}^+ is a reflexive object in the category **SD**.

Proof. As anticipated, there is a continuous isomorphism $\theta : (\mathcal{A} \Rightarrow \mathcal{A})^+ \rightarrow [\mathcal{A}^+ \rightarrow \mathcal{A}^+]$ and by Proposition 2.2 the domain $(\mathcal{A} \Rightarrow \mathcal{A})^+$ can be embedded into \mathcal{A}^+ via the retraction pair $((\phi_A)_\bullet, (\phi_A)^\bullet)$. Therefore $(\theta \circ (\phi_A)_\bullet, \theta^{-1} \circ (\phi_A)^\bullet)$ is the desired retraction pair in the category **SD**. □

We set $\mathbf{A}^+ = (\mathcal{A}^+, \theta \circ (\phi_A)_\bullet, \theta^{-1} \circ (\phi_A)^\bullet)$ and call \mathbf{A}^+ an *i-model*. Of course, since \mathbf{A}^+ is a reflexive object in **SD**, then \mathbf{A}^+ is also a λ -model and λ -terms are interpreted as elements of \mathcal{A}^+ (i.e. as points of \mathcal{A}) as follows:

$$\begin{aligned} \llbracket x_i \rrbracket_\rho^{\mathbf{A}^+} &= \rho(x) \\ \llbracket \lambda y. M \rrbracket_\rho^{\mathbf{A}} &= \{ \phi_A(a, \alpha) : \alpha \in \llbracket M \rrbracket_{\rho[y:=a]}^{\mathbf{A}^+} \} \downarrow_A \\ \llbracket MN \rrbracket_\rho^{\mathbf{A}} &= \{ \beta \in A : \exists a \subseteq_f \llbracket N \rrbracket_\rho^{\mathbf{A}^+}. (a, \beta) \in \{ (a', \beta') : \phi_A(a', \beta') \in \llbracket M \rrbracket_\rho^{\mathbf{A}^+} \} \downarrow_{A \Rightarrow A} \} \end{aligned}$$

The λ -model structure associated to the *i-model* \mathbf{A}^+ is the following. The basic combinators are $\mathbf{k}^{\mathbf{A}^+} = \llbracket \lambda xy. x \rrbracket_\rho^{\mathbf{A}^+}$ and $\mathbf{s}^{\mathbf{A}^+} = \llbracket \lambda xyz. xz(yz) \rrbracket_\rho^{\mathbf{B}^+}$, and the application operation is given by

$$u \cdot v = \{ \beta \in A : \exists a \subseteq_f v. (a, \beta) \in \{ (a', \beta') : \phi_A(a', \beta') \in u \} \downarrow_{A \Rightarrow A} \}$$

for all points u, v .

2.4.1 Well-known instances of i-webs

An *extended abstract type structure* (EATS, for short, [13, Def. 1.1]) is a partially ordered algebra $(A, \wedge, \rightarrow, \omega)$, where “ \wedge ” and “ \rightarrow ” are binary operations and “ ω ” is nullary one. Then the structure $\mathcal{A} = (A, \mathcal{P}_f(A), \vdash, \omega)$, where $a \vdash \alpha$ iff $(\wedge a) \leq \alpha$, is an information system. For two EATSs $(A, \wedge_A, \rightarrow_A, \omega_A)$ and $(B, \wedge_B, \rightarrow_B, \omega_B)$ a *bf-morphism* $\psi : \mathcal{A} \rightarrow \mathcal{B}$ between the corresponding information systems is a function satisfying $\alpha \leq_A \alpha'$ iff $\psi(\alpha) \leq_B \psi(\alpha')$. Recall from [13, Def. 2.12, Thm. 2.13] that the Filter models living in the Scott semantics are obtained by taking the set of filters of EATSs satisfying the following condition:

$$(*) \quad \bigwedge_{i=1}^n (\alpha_i \rightarrow \beta_i) \leq \gamma \rightarrow \delta, \text{ then } (\bigwedge_{i \in \{i: \gamma \leq \alpha_i\}} \beta_i) \leq \delta$$

In such a case, defining $\phi : \mathcal{P}_f(A) \times A \rightarrow A$ by $\phi(a, \alpha) = (\bigwedge a) \rightarrow \alpha$ one obtains a b-morphism and hence an i-web $\mathbf{A} = (\mathcal{A}, \phi_A)$ and the corresponding filter model is exactly the i-model \mathbf{A}^+ (see [11] for the details).

In Larsen & Winskel [19] the definition of information system is slightly different: there is no special token v . We remark that the corresponding class of i-models generated by the two definitions is the same. We adopt Scott's original definition just for technical reasons. With Larsen & Winskel's definition we can capture some other known classes of models, as illustrated below.

A *preordered set with coherence* (pc-set, for short) is a triple (A, \leq, \approx) , where A is a non-empty set, \leq is a preorder on A and \approx is a coherence (i.e., a reflexive, symmetric relation on A) compatible with the preorder (see [6, Def. 120]). A pc-set “is” an information system $\mathcal{A} = (A, \mathcal{P}_f^{\text{coh}}(A), \vdash)$, where $\mathcal{P}_f^{\text{coh}}(A)$ is the set of finite coherent subsets of A and $a \vdash \alpha$ iff $\exists \beta \in a. \beta \geq \alpha$. A *pc-web* (see [6, Def. 153]) is determined by a pc-set together with a map $\phi : \mathcal{P}_f^{\text{coh}}(A) \times A \rightarrow A$ satisfying:

- (1) $\phi(a, \alpha) \approx \phi(b, \beta)$ iff $(a \cup b \in \mathcal{P}_f^{\text{coh}}(A) \Rightarrow \alpha \approx \beta)$
- (2) if $\phi(a, \alpha) \leq \phi(b, \beta)$, then $\alpha \leq \beta$ and $(\forall \gamma \in b \exists \delta \in a. \gamma \leq \delta)$.

A pc-web is a particular instance of i-web and properties (1),(2) say exactly that ϕ is a b-morphism. Krivine webs [6, Sec. 5.6.2] are pc-webs in which $\approx = A \times A$ (so that $\mathcal{P}_f^{\text{coh}}(A) = \mathcal{P}_f(A)$). *Total pairs* [6, Sec. 5.5] are Krivine webs in which \leq is the equality: in fact in this the requirement of ϕ to be a b-morphism boils down to injectivity. Therefore a total pair is simply defined as a set A together with an injection $i_A : \mathcal{P}_f(A) \times A \rightarrow A$; the underlying information system is $\mathcal{A} = (A, \mathcal{P}_f(A), \supseteq)$. The *graph model* associated to the total pair is then the i-model \mathbf{A}^+ , obtained by taking the powerset of A (see [6, Def. 120]). There is usually some ambiguity in the terminology since by “graph model” sometimes is meant the total pair (as in [8], for example) underlying the model itself.

3 Minimal models: general results

In general, given a class \mathcal{C} of λ -models, a natural question to be asked is whether there exists a member \mathbf{A} of \mathcal{C} such that $\text{Eq}(\mathbf{A})$ is contained in the theories of all other members of \mathcal{C} : one such model \mathbf{A} is called *minimal* in \mathcal{C} . This point was raised in print by C. Berline [6] who was mainly referring to the classes of webbed models of λ -calculus. If a positive answer is obtained, usually it is done by purely semantical methods and $\text{Eq}(\mathbf{A})$ does not need to be characterised in the syntactical sense: this is the case of Di Giannantonio et al. [14], in which the authors prove that the class all extensional reflexive CPOs has a minimal model. Of course if one is able to gather enough information about $\text{Eq}(\mathbf{A})$, then one may be in the position to answer the related completeness question for the class \mathcal{C} : is $\lambda\beta$ (or $\lambda\beta\eta$) a theory induced by a member of \mathcal{C} ? An example of result of this kind can be found again in [14], where the authors construct a model with theory $\lambda\beta\eta$ in the ω_1 -semantics.

In this section we give general conditions for a class \mathcal{C} of λ -models under which we have the guarantee that \mathcal{C} has a minimal model. In the forthcoming section 4 we will apply this general result to the class of i-models and some of its well-known classes of models.

Definition 3.1. A class \mathcal{C} of λ -models has the finite intersection property (*fip*, for short) if for every two members \mathbf{A}, \mathbf{B} of \mathcal{C} , there exists a member \mathbf{C} of \mathcal{C} such that $\text{Eq}(\mathbf{C}) \subseteq \text{Eq}(\mathbf{A}) \cap \text{Eq}(\mathbf{B})$.

For example the class of all λ -models has the fip, and in general every class closed under direct products has the fip. Every subclass which is axiomatized over the λ -models by first-order universal sentences has the fip, but of course these conditions do not hold in general for the classes of webbed models, e.g. for the i-models. We will see that they do hold for the filter models.

The *fip* is a property which is weaker than the closure under direct products. Of course a class which is closed under arbitrary (non-empty) direct products has a minimal model. The next definition isolates a property that, together with the *fip*, can overcome the lack of direct products and guarantee the existence of minimal models.

Definition 3.2. A class \mathcal{C} of λ -models has the *ultraproduct property* (*upp*, for short) if for every non-empty family $\{\mathbf{A}_i\}_{i \in I}$ of members of \mathcal{C} and for every proper ultrafilter U of sets on $\mathcal{P}(I)$ the ultraproduct $(\prod_{i \in I} \mathbf{A}_i)/U$ can be embedded into a member of \mathcal{C} .

For example the class of all λ -models has the *upp*, and in general every class closed under ultraproducts has the *upp*. Every subclass which is axiomatized over the λ -models by first-order sentences has the *upp*, but of course these conditions do not hold in general for the known classes of webbed models, e.g. for the *i*-models.

Theorem 3.1. Let \mathcal{C} be a class of λ -models having both the *fip* and the *upp*. Then \mathcal{C} has a minimal model.

Proof. Let I be the set of all equations e between closed combinatory terms for which there exists a model \mathbf{A} in \mathcal{C} such that $\mathbf{A} \models e$. For every $e \in I$, consider the set $K_e = \{J \subseteq_f I : e \in J\}$. Since $K_e \cap K_{e'} = \{J \subseteq_f I : e, e' \in J\} \neq \emptyset$ for all $e, e' \in I$, then there exists a non-principal ultrafilter U on $\mathcal{P}_f(I)$ containing the family $(K_e : e \in I)$. By the finite intersection property of the class \mathcal{C} , for every $J \subseteq_f I$ there exists a model \mathbf{A}_J in \mathcal{C} such that $e \notin \text{Eq}(\mathbf{A}_J)$ for every $e \in J$. Let $\{\mathbf{A}_J\}_{J \subseteq_f I}$ be the family composed by these models and consider the ultraproduct $\mathbf{P}_U = (\prod_{J \subseteq_f I} \mathbf{A}_J)/U$. Let $e \in I$ be a closed equation and let $X_e = \{J \subseteq_f I : \mathbf{A}_J \models e\}$. Then $X_e \supseteq K_e \in U$, so that X_e belongs to the ultrafilter U . Since e is a closed first-order formula, by Łoś Theorem 2.1 $\mathbf{P}_U \models e$. Since e was an arbitrary equation in I , we have that $\mathbf{P}_U \models e$ for every $e \in I$, so that $\text{Eq}(\mathbf{P}_U) \subseteq \bigcap_{\mathbf{A} \in \mathcal{C}} \text{Eq}(\mathbf{A})$. Finally, since the class \mathcal{C} has the ultraproduct property, then there exists a model \mathbf{B} in \mathcal{C} such that \mathbf{P}_U embeds into \mathbf{B} . Then $\text{Eq}(\mathbf{B}) = \text{Eq}(\mathbf{P}_U) \subseteq \bigcap_{\mathbf{A} \in \mathcal{C}} \text{Eq}(\mathbf{A}) \subseteq \text{Eq}(\mathbf{B})$ and we get the desired conclusion. \square

Corollary 3.2. Let \mathcal{C} be a class of λ -models which has the *fip* and is closed under ultraproducts. Then \mathcal{C} has a minimal model.

We conclude the section by giving some other general results that can be proved by just assuming the *fip* and the *upp* for a class \mathcal{C} of λ -models. In particular we can prove a compactness theorem for lambda-theories whose equations hold in members of \mathcal{C} . Another result that can be proved is that if there exists a λ -term that can be proved easy in \mathcal{C} , then there exists a continuum of \mathcal{C} -theories i.e. there are uncountably many different lambda-theories induced by models of the class \mathcal{C} .

Theorem 3.3 (Compactness). Let \mathcal{C} be a class of λ -models having the *upp*, and let E be a set of equations between closed λ -terms. If every finite subset of E is satisfied by a member of \mathcal{C} , then E itself is satisfied by a member of \mathcal{C} .

Proof. For every $J \subseteq_f E$, let $K_J = \{I \subseteq_f E : J \subseteq I\}$ and let $\mathbf{A}_J \in \mathcal{C}$ be a model satisfying J . Let U be a proper ultrafilter on $\mathcal{P}_f(E)$ containing K_J for every $J \subseteq_f E$. Then the ultraproduct $(\prod_{J \subseteq_f E} \mathbf{A}_J)/U$ satisfies E . Finally by the *upp* there exists a model \mathbf{B} in \mathcal{C} such that $(\prod_{J \subseteq_f E} \mathbf{A}_J)/U$ embeds into \mathbf{B} , and thus has the same lambda-theory. We conclude that \mathbf{B} satisfies E . \square

Let \mathcal{C} be a class of λ -models. A closed λ -term M is \mathcal{C} -easy if for every closed λ -term N there exists a member \mathbf{B} of \mathcal{C} such that $\llbracket M \rrbracket^{\mathbf{B}} = \llbracket N \rrbracket^{\mathbf{B}}$.

Theorem 3.4. Let \mathcal{C} be a class of λ -models having the *upp* such that there exists a \mathcal{C} -easy λ -term. Then there exist uncountably many \mathcal{C} -theories.

Proof. Let M be a \mathcal{C} -easy λ -term. For $n \geq 1$, we let $\pi_n \equiv \lambda x_1 \dots x_n. x_n$. We prove that for every $n \geq 1$ the term $M\pi_n$ is \mathcal{C} -easy.

Let $X = (N_n)_{n \geq 1}$ be an arbitrary infinite sequence of closed $\beta\eta$ -normal λ -terms and define $E(X) = \{M\pi_n = N_n : n \geq 1\}$. Let $K = \{M\pi_{n_1} = N_{n_1}, \dots, M\pi_{n_k} = N_{n_k}\}$ be a finite subset of $E(X)$. Without loss of generality, we may assume that $n_1 < \dots < n_k$. Let y be a fresh variable and define inductively

$$Z_1 := y \underbrace{\mathbf{I} \dots \mathbf{I}}_{n_1-1} N_{n_1}; \quad Z_{m+1} := Z_m \underbrace{\mathbf{I} \dots \mathbf{I}}_{n_{m+1}-n_m-1} N_{n_{m+1}}$$

Now set $Z = \lambda y. Z_k$. Since M is \mathcal{C} -easy, then there is a member \mathbf{A} of \mathcal{C} such that $\mathbf{A} \models M = Z$. Therefore $\mathbf{A} \models M\pi_{n_i} = Z\pi_{n_i} = N_{n_i}$ for all $i = 1, \dots, k$ so that $K \subseteq \text{Eq}(\mathbf{A})$. Since every finite subset of $E(X)$ is satisfied by a member of \mathcal{C} , then by Theorem 3.3 $E(X)$ itself is satisfied by a member of \mathcal{C} , i.e. there exists a member \mathbf{A}_X of \mathcal{C} such that $E(X) \subseteq \text{Eq}(\mathbf{A}_X)$. Moreover if X and Y are two different infinite sequences of closed $\beta\eta$ -normal λ -terms, then $\text{Eq}(\mathbf{A}_X) \neq \text{Eq}(\mathbf{A}_Y)$. The result then follows from the fact that there are uncountably many infinite sequences of closed $\beta\eta$ -normal λ -terms. \square

4 Applications

In the present section we apply the general results developed in §3. In particular we prove that the class of i-models has both the finite intersection property and the ultraproduct property. Then we comment on how these general results also apply to other well-known classes of webbed models.

4.1 Finite intersection property for i-models

The goal of the first part of this section is to prove that for every pair $\mathbf{A}_1, \mathbf{A}_2$ of i-webs there exists an i-web \mathbf{B} such that $\text{Eq}(\mathbf{B}^+) \subseteq \text{Eq}(\mathbf{A}_1^+) \cap \text{Eq}(\mathbf{A}_2^+)$. Such result would be trivial if the categorical product $\mathcal{A}_1 \& \mathcal{A}_2$ could always be endowed with a suitable structure of i-web, but this is not the case. The best that we can do in general is to make $\mathcal{A}_1 \& \mathcal{A}_2$ into a *partial i-web*. A partial i-web in general is a pair $\mathbf{A} = (\mathcal{A}, \phi_A)$, where $\phi_A : \mathcal{A} \Rightarrow \mathcal{A} \multimap \mathcal{A}$ is a partial b-morphism. In particular we can set

$$\phi(a, \alpha) = \begin{cases} (v_{A_1}, v_{A_2}) & \text{if } a \subseteq \{(v_{A_1}, v_{A_2})\} \text{ and } \alpha = (v_{A_1}, v_{A_2}) \\ (v_{A_1}, \phi_{A_2}(\text{snd}^*(a), \text{snd}(\alpha))) & \text{if } a \cup \{\alpha\} \subseteq_f \{v_{A_1}\} \times A_2 \\ (\phi_{A_1}(\text{fst}^*(a), \text{fst}(\alpha)), v_{A_2}) & \text{if } a \cup \{\alpha\} \subseteq_f A_1 \times \{v_{A_2}\} \end{cases}$$

obtaining that $\mathbf{A}_1 \& \mathbf{A}_2 = (\mathcal{A}_1 \& \mathcal{A}_2, \phi)$ is a partial i-web. A partial i-web does not give in general an i-model, but we can complete it to an i-web through a limit process that involves countably many extension steps.

We say that \mathcal{B} is an *extension* of \mathcal{S} , notation $\mathcal{S} \preceq \mathcal{B}$, if $S \subseteq B$, $\text{Con}_S = \text{Con}_B \cap \mathcal{P}_f(S)$, $\vdash_S = \vdash_B \cap (\text{Con}_S \times S)$. We say that \mathbf{B} is an extension of \mathbf{S} , notation $\mathbf{S} \preceq \mathbf{B}$, if $\mathcal{S} \preceq \mathcal{B}$ and ϕ_S is the restriction of ϕ_B to $\text{Con}_S \times S$.

Let us call \mathbf{B} the extension of result of the (yet undefined) completion process. Of course \mathbf{B} must be somehow related to the original i-webs \mathbf{A}_1 and \mathbf{A}_2 . In particular, we want that for every closed λ -term M if $(v_{A_1}, \beta) \in \llbracket M \rrbracket^{\mathbf{B}^+}$ (resp. $(\alpha, v_{A_2}) \in \llbracket M \rrbracket^{\mathbf{B}^+}$), then $\beta \in \llbracket M \rrbracket^{\mathbf{A}_1^+}$ (resp. $\alpha \in \llbracket M \rrbracket^{\mathbf{A}_2^+}$) because this will guarantee that $\text{Eq}(\mathbf{B}^+) \subseteq \text{Eq}(\mathbf{A}_1^+) \cap \text{Eq}(\mathbf{A}_2^+)$. We will achieve this property by means of the notion of *f-morphism* of partial i-webs.

Notation. Let $f : A \rightarrow B$ be a function. We define $f^* : \mathcal{P}_f(B) \rightarrow \mathcal{P}_f(C)$ and $\tilde{f} : (\mathcal{P}_f(B) \times B) \rightarrow (\mathcal{P}_f(C) \times C)$ as follows: $f^*(b) = \{f(\beta) \mid \beta \in b, \beta \in \text{do}(f)\}$ and $\tilde{f}(b, \beta) = (f^*(b), f(\beta))$. Hence $\tilde{f}^* :$

$\mathcal{P}_f(\mathcal{P}_f(B) \times B) \rightarrow \mathcal{P}_f(\mathcal{P}_f(C) \times C)$. If f is a partial function, we write $\text{do}(f)$ to indicate the domain of f .

Definition 4.1 ([10]). *Let \mathbf{B}, \mathbf{C} be partial i-webs. An f-morphism from \mathbf{B} to \mathbf{C} is an f-morphism $\psi : \mathcal{B} \rightarrow \mathcal{C}$ satisfying the following additional property:*

$$(iMo) \quad \text{if } (a, \beta) \in \text{do}(\phi_B), \text{ then } (\psi^*(a), \psi(\beta)) \in \text{do}(\phi_C) \text{ and } \psi(\phi_B(a, \beta)) = \phi_C(\psi^*(a), \psi(\beta))$$

The following proposition explains that, in general, f-morphisms of i-webs “commute” well to the interpretation of λ -terms.

Proposition 4.1 ([10]). *Let \mathbf{B}, \mathbf{C} be i-webs, let $\psi : \mathbf{B} \rightarrow \mathbf{C}$ be an f-morphism of i-webs, and let M be a closed λ -term. If $\alpha \in \llbracket M \rrbracket^{\mathbf{B}^+}$, then $\psi(\alpha) \in \llbracket M \rrbracket^{\mathbf{C}^+}$.*

We remark that the two projection functions fst and snd are f-morphisms of partial i-webs from $\mathbf{A}_1 \& \mathbf{A}_2$ to \mathbf{A}_1 and \mathbf{A}_2 , respectively.

Our goal now is to construct a series of triples $\{(\mathbf{S}_n, \psi_n^1, \psi_n^2)\}_{n \geq 0}$ such that $\mathbf{S}_n \preceq \mathbf{S}_{n+1}$ and $\psi_n^i : \mathbf{S}_n \rightarrow \mathbf{A}_i$ ($i = 1, 2$) is an f-morphism of partial i-webs such that ψ_{n+1}^i extends ψ_n^i ($i = 1, 2$). The idea is that the input parameter of the whole construction is the triple $(\mathbf{S}_0, \psi_0^1, \psi_0^2)$ where $\mathbf{S}_0 := \mathbf{A}_1 \& \mathbf{A}_2$, $\psi_0^1 = \text{fst}$, and $\psi_0^2 = \text{snd}$. All subsequent triples are constructed via an algorithm that, given $(\mathbf{S}_n, \psi_n^1, \psi_n^2)$ as input, returns $(\mathbf{S}_{n+1}, \psi_{n+1}^1, \psi_{n+1}^2)$. The union of all partial i-webs and all f-morphisms of partial i-webs finally gives an i-web \mathbf{S}_ω (called *completion*) and two f-morphisms ψ_ω^i ($i = 1, 2$) of i-webs that allow to show that $\text{Eq}(\mathbf{S}_\omega^+) \subseteq \text{Eq}(\mathbf{A}_1^+) \cap \text{Eq}(\mathbf{A}_2^+)$.

The 0-th stage of the completion process, i.e., the triple $(\mathbf{S}_0, \psi_0^1, \psi_0^2)$ has already been described. Now assuming we reached stage n , we show how to carry on with stage $n + 1$.

Definition 4.2. • $S_{n+1} = S_n \cup \overline{\text{do}}(\phi_{S_n})$

- $\text{Cons}_{S_{n+1}}$ is the smallest family of sets $x \subseteq_f S_n \cup \overline{\text{do}}(\phi_{S_n})$ such that either
 - (1) there exist $a \in \text{Con}_n$ and $X \in \text{Cons}_{S_n \Rightarrow S_n}$ such that $X \subseteq \overline{\text{do}}(\phi_{S_n})$ and $x = a \cup X$ and $\psi_n^{i*}(a) \cup \phi_{A_i}^*(\widetilde{\psi_n^{i*}}(X)) \in \text{Con}_{A_i}$ ($i = 1, 2$) or
 - (2) there exists $X \in \text{Cons}_{S_n \Rightarrow S_n}$ such that $x \subseteq_f (X \cap \overline{\text{do}}(\phi_{S_n})) \cup (\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n}))) \downarrow_{S_n}$
- $a \vdash_{S_{n+1}} \alpha$ iff either $a \cap S_n \vdash_{S_n} \alpha$ or $\alpha \in a$
- $v_{S_{n+1}} = v_{S_n}$
- $\phi_{S_{n+1}}(a, \alpha) = \begin{cases} \phi_{S_n}(a, \alpha) & \text{if } (a, \alpha) \in \text{do}(\phi_{S_n}) \\ (a, \alpha) & \text{if } (a, \alpha) \in \overline{\text{do}}(\phi_{S_n}) \\ \text{undefined} & \text{if } (a, \alpha) \in (S_{n+1} \Rightarrow S_{n+1}) - (S_n \Rightarrow S_n) \end{cases}$
- for $i = 1, 2$ we set $\psi_{n+1}^i(\alpha) = \begin{cases} \psi_n^i(\alpha) & \text{if } \alpha \in S_n \\ \phi_{A_i}(\psi_n^{i*}(b), \psi_n^i(\beta)) & \text{if } \alpha = (b, \beta) \in S_{n+1} - S_n \end{cases}$

Theorem 4.2. *We have that*

- (i) $\mathcal{S}_{n+1} = (S_{n+1}, \text{Cons}_{S_{n+1}}, \vdash_{S_{n+1}}, v_{S_{n+1}})$ is an information system such that $\mathcal{S}_n \preceq \mathcal{S}_{n+1}$,
- (ii) $\mathbf{S}_{n+1} = (\mathcal{S}_{n+1}, \phi_{S_{n+1}})$ is a partial i-web such that $\mathbf{S}_n \preceq \mathbf{S}_{n+1}$,
- (iii) $\psi_{n+1}^i : \mathbf{S}_{n+1} \rightarrow \mathbf{A}_i$ ($i = 1, 2$) is an f-morphism of partial i-webs.

Proof. (i) We show that \mathcal{S}_{n+1} is an information system, checking the four properties of Definition ??.

- (I1) Suppose $a \in \text{Con}_{S_{n+1}}$ and $a \vdash_{S_{n+1}} b$. If a has been added to $\text{Con}_{S_{n+1}}$ by clause (1), then exists $i \in \{1, 2\}$, $a' \in \text{Con}_{S_n}$ and $X \in \text{Con}_{S_n \Rightarrow S_n}$ such that $X \subseteq \overline{\text{do}}(\phi_{S_n})$ and $a = a' \cup X$ and $\psi_n^{i*}(a') \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X)) \in \text{Con}_{A_i}$. Since $a \vdash_{S_{n+1}} b$, then $b = b' \cup X$, for some $b' \in \text{Con}_{S_n}$ such that $a' \vdash_{S_n} b'$. Now ψ_n^i is a morphism, so that $\psi_n^{i*}(b') \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X)) \in \text{Con}_{A_i}$. Therefore b is added to $\text{Con}_{S_{n+1}}$ by clause (1).

If a has been added to $\text{Con}_{S_{n+1}}$ by clause (2), then also b is added to $\text{Con}_{S_{n+1}}$ by the same clause.

- (I2) If $\alpha \in a$, then $a \vdash_{S_{n+1}} \alpha$ by definition of $\vdash_{S_{n+1}}$.
- (I3) Suppose $a \vdash_{S_{n+1}} \{\alpha_1, \dots, \alpha_k\}$ and $\{\alpha_1, \dots, \alpha_k\} \vdash_{S_{n+1}} \gamma$. If $\gamma \in \{\alpha_1, \dots, \alpha_k\}$ then clearly $a \vdash_{S_{n+1}} \gamma$. Otherwise $\{\alpha_1, \dots, \alpha_k\} \cap S_n \vdash_{S_n} \gamma$ and since $a \cap S_n \vdash_{S_n} \{\alpha_1, \dots, \alpha_k\} \cap S_n$ we can conclude using the property (I3) of \mathcal{S}_n .
- (I4) Immediate.

Finally it is immediate to see that $\mathcal{S}_n \preceq \mathcal{S}_{n+1}$.

(ii) Note that the fact that $\mathcal{S}_n \preceq \mathcal{S}_{n+1}$ automatically implies $\mathcal{S}_n \Rightarrow \mathcal{S}_n \preceq \mathcal{S}_{n+1} \Rightarrow \mathcal{S}_{n+1}$. Now we prove that $\phi_{S_{n+1}} : \mathcal{S}_n \Rightarrow \mathcal{S}_n \rightarrow \mathcal{S}_{n+1}$ is a total b-morphism, so that it is automatically a partial b-morphism from $\mathcal{S}_{n+1} \Rightarrow \mathcal{S}_{n+1}$ to \mathcal{S}_{n+1} .

- (Mo) We must show that $X \in \text{Con}_{S_n \Rightarrow S_n}$ iff $(X \cap \overline{\text{do}}(\phi_{S_n})) \cup (\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n}))) \in \text{Con}_{S_{n+1}}$. If $X \in \text{Con}_{S_n \Rightarrow S_n}$, then $(X \cap \overline{\text{do}}(\phi_{S_n})) \cup (\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n})))$ is in $\text{Con}_{S_{n+1}}$ by clause (2).

Let $x = (X \cap \overline{\text{do}}(\phi_{S_n})) \cup (\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n}))) \in \text{Con}_{S_{n+1}}$. If x is added to $\text{Con}_{S_{n+1}}$ by clause (1), then there exist $i \in \{1, 2\}$, $a \in \text{Con}_n$ and $Y \in \text{Con}_{S_n \Rightarrow S_n}$ such that $Y \subseteq \overline{\text{do}}(\phi_{S_n})$ and $x = a \cup Y$ and $\psi_n^{i*}(a) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(Y)) \in \text{Con}_{A_i}$. Therefore $Y = (X \cap \overline{\text{do}}(\phi_{S_n}))$ and $a = (\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n})))$. Now we have

$$\begin{aligned} \psi_n^{i*}(a) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(Y)) &= \psi_n^{i*}((\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n})))) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*((X \cap \overline{\text{do}}(\phi_{S_n})))) \\ &= \phi_{A_i}^*(\widetilde{\psi_n^i}^*((X \cap \text{do}(\phi_{S_n})))) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*((X \cap \overline{\text{do}}(\phi_{S_n})))) \\ &= \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X)) \end{aligned}$$

Since $\psi_n^{i*}(a) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(Y))$ is in Con_{A_i} by hypothesis, then so is $\phi_{A_i}^*(\widetilde{\psi_n^i}^*(X))$ and since both ϕ_{A_i} and ψ_n^i are morphisms of information systems, then so is their composition $\phi_{A_i} \circ \psi_n^i$, meaning that $X \in \text{Con}_{S_n \Rightarrow S_n}$.

If x is added to $\text{Con}_{S_{n+1}}$ by clause (2), then evidently $X \in \text{Con}_{S_n \Rightarrow S_n}$.

- (bMo) We must show that $\phi_{S_{n+1}}^*(X) \vdash_{S_{n+1}} \phi_{S_{n+1}}(a, \alpha)$ implies $X \vdash_{S_{n+1} \Rightarrow S_{n+1}} (a, \alpha)$. There are two cases to be dealt with. If $(a, \alpha) \in \text{do}(\phi_{S_n})$, then $\phi_{S_n}^*(X) \cap S_n \vdash_{S_n} \phi_{S_n}(a, \alpha)$ and we derive $\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n})) \vdash_{S_n} \phi_{S_n}(a, \alpha)$ so that by (bMo) for ϕ_{S_n} we have that $X \cap \text{do}(\phi_{S_n}) \vdash_{S_n \Rightarrow S_n} (a, \alpha)$ and hence $X \vdash_{S_n \Rightarrow S_n} (a, \alpha)$.

If $(a, \alpha) \notin \text{do}(\phi_{S_n})$, then $(a, \alpha) = \phi_{S_{n+1}}(a, \alpha) \in \phi_{S_{n+1}}^*(X)$, so that $(a, \alpha) \in X$ and thus $X \vdash_{S_n \Rightarrow S_n} (a, \alpha)$.

- (iii) Now we prove that ψ_{n+1}^i ($i = 1, 2$) is an f-morphism of i-webs.

- (Mo) (\Rightarrow) Suppose $x \in \text{Con}_{S_{n+1}}$. We consider the clauses (1) and (2) of the definition of $\text{Con}_{S_{n+1}}$.

If x is added by clause (1), i.e. $x = a \cup X$ for suitable a and X , then $\psi_{n+1}^{i*}(x) = \psi_n^{i*}(a) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X)) \in \text{Con}_{A_i}$, by clause (1) itself.

If x is added by clause (2), then $x \subseteq_f (X \cap \overline{\text{do}}(\phi_{S_n})) \cup (\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n}))) \downarrow_{S_n}$, for some $X \in \text{Con}_{S_n \Rightarrow S_n}$. Now let $y = (X \cap \overline{\text{do}}(\phi_{S_n})) \cup \phi_{S_n}^*(X \cap \text{do}(\phi_{S_n}))$. We first observe that

$$\begin{aligned} \psi_{n+1}^{i*}(y) &= \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X \cap \overline{\text{do}}(\phi_{S_n}))) \cup \psi_n^{i*}(\phi_{S_n}^*(X \cap \text{do}(\phi_{S_n}))) \\ &= \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X \cap \overline{\text{do}}(\phi_{S_n}))) \cup \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X \cap \text{do}(\phi_{S_n}))) \\ &= \phi_{A_i}^*(\widetilde{\psi_n^i}^*(X)) \end{aligned}$$

This proves that $\psi_{n+1}^{i*}(y) \in \text{Con}_{A_i}$. Now using property (fMo) ψ_n^i we obtain that $\psi_{n+1}^{i*}(y) \vdash_{A_i} \psi_{n+1}^{i*}(x)$, and hence $\psi_{n+1}^{i*}(x) \in \text{Con}_{A_i}$.

(\Leftarrow) By the very definition of $\text{Con}_{S_{n+1}}$, in particular by the clause (1).

(fMo) Suppose $a \vdash_{S_{n+1}} \alpha$. If $\alpha \in a$, then of course $\psi_{n+1}^{i*}(a) \vdash_{A_i} \psi_{n+1}^i(\alpha)$. If $a \cap S_n \vdash_{S_n} \alpha$, then

$$\psi_{n+1}^{i*}(a) = \psi_{n+1}^{i*}(a - S_n) \cup \psi_n^{i*}(a \cap S_n) \vdash_{A_i} \psi_n^i(a \cap S_n) \vdash_{A_i} \psi_n^i(\alpha)$$

(iMo) Let $(a, \alpha) \in S_n \Rightarrow S_n$. Then $\psi_{n+1}^i(\phi_{S_{n+1}}(a, \alpha)) = \phi_{A_i}(\psi_n^{i*}(a), \psi_n^i(\alpha)) = \phi_{A_i}(\psi_{n+1}^i(a), \psi_{n+1}^i(\alpha))$, by definition of ψ_{n+1}^i and the fact that it extends ψ_n^i .

□

The *completion* of the triple $(\mathbf{A}_1 \& \mathbf{A}_2, \pi_1, \pi_2)$ is the triple $(\mathbf{S}_\omega, \psi_\omega^1, \psi_\omega^2)$, where $\mathcal{S}_\omega = (S_\omega, \text{Con}_{S_\omega}, \vdash_{S_\omega}, \nu_{S_\omega})$ and $\mathbf{S}_\omega = (\mathcal{S}_\omega, \phi_{S_\omega})$ are given by the following data:

$$\begin{aligned} S_\omega &:= \bigcup_{m < \omega} S_m & \text{Con}_{S_\omega} &:= \bigcup_{m < \omega} \text{Con}_{S_m} & \vdash_{S_\omega} &:= \bigcup_{m < \omega} \vdash_{S_m} \\ \nu_{S_\omega} &:= \nu_{A_1 \& A_2} & \phi_{S_\omega} &:= \bigcup_{m < \omega} \phi_{S_m} & \psi_\omega^i &:= \bigcup_{m < \omega} \psi_m^i \quad (i = 1, 2) \end{aligned}$$

Lemma 4.3. \mathbf{S}_ω is an *i-web* and $\psi_\omega^i : \mathbf{S}_\omega \rightarrow \mathbf{A}_i$ ($i = 1, 2$) is an *f-morphism of i-webs*.

Proof. Indeed \mathcal{S}_ω is an information system as a consequence of Theorem 4.2(i). Moreover the map ϕ_{S_ω} is total and it is easy to prove that it is a b-morphism from $\mathcal{S}_\omega \Rightarrow \mathcal{S}_\omega$ using the fact that for every n the map $\phi_{S_{n+1}}$ is a partial b-morphism (Theorem 4.2(ii)). Similarly one can prove that ψ_ω^i is an f-morphism of i-webs from \mathbf{S}_ω to \mathbf{A}_i ($i = 1, 2$) simply using the fact that for every n the map ψ_n^i is an f-morphism from the partial i-web \mathbf{S}_n to the i-webs \mathbf{A}_i ($i = 1, 2$) (Theorem 4.2(iii)). □

Theorem 4.4. $\text{Eq}(\mathbf{S}_\omega^+) \subseteq \text{Eq}(\mathbf{A}_1^+) \cap \text{Eq}(\mathbf{A}_2^+)$.

Proof. Suppose $M = N \notin \text{Eq}(\mathbf{A}_1^+) \cap \text{Eq}(\mathbf{A}_2^+)$. Suppose, w.l.o.g., that $M = N \notin \text{Eq}(\mathbf{A}_1^+)$. Then there exists $\alpha \in A_1$ such that $\alpha \in \llbracket M \rrbracket^{\mathbf{A}_1^+} - \llbracket N \rrbracket^{\mathbf{A}_2^+}$. It is not difficult to check that $\alpha \in \llbracket M \rrbracket^{\mathbf{A}_1^+}$ implies $(\alpha, \nu_{A_2}) \in \llbracket M \rrbracket^{\mathbf{S}_\omega^+}$, since \mathbf{S}_ω extends $\mathbf{A}_1 \& \mathbf{A}_2$. Now suppose, by way of contradiction, that $(\alpha, \nu_{A_2}) \in \llbracket N \rrbracket^{\mathbf{S}_\omega^+}$. Since $\psi_\omega^1(\alpha, \nu_{A_2}) = \alpha$, by Proposition 4.1 we have that $\alpha \in \llbracket N \rrbracket^{\mathbf{A}_1^+}$, which is a contradiction. This proves that $(\alpha, \nu_{A_2}) \in \llbracket M \rrbracket^{\mathbf{S}_\omega^+} - \llbracket N \rrbracket^{\mathbf{S}_\omega^+}$, so that $M = N \notin \text{Eq}(\mathbf{S}_\omega^+)$. □

In §2.4.1 we indicate how some of the most known classes of webbed models are recovered as particular instances of i-models (more details for Filter Models are in [11]). Along these lines the notion of partial i-web generalizes those of *partial pair* [6] (related to graph models) as well as the notions of partial webs of the other types.

The idea of partial pair and of a completion for obtaining a graph model generalizes the construction of the Engeler model and the of the Plotkin–Scott \mathcal{P}_ω model. It was initiated by Longo in [20] and further developed and applied by Kerth [17]. Definition 4.2 is the core of a completion of i-webs that

further generalizes Longo and Kerth's work. As such, it can be adapted case by case so that the entire completion adapts to the various instances of i-webs in the sense that if we start with partial pair, at the end we obtain a total pair, if we start with a partial pcs-web, we end up in a total pcs-web etc.

Of course Theorem 4.4 proves the finite intersection property for the class of i-models, but in view of the above discussion it can also give proofs of the finite intersection property for the subclasses of models mentioned in section 2.4.1.

For the particular case of graph models the fip was proved by Bucciarelli&Salibra [9, 8], via a construction that they call *weak product* which has the same spirit of our completion method. For the other classes of models the fip was not known to hold. For the particular case of filter models one may prove the fip as a simple consequence of the closure of filter models under the construction of direct products, a result that does not appear in the literature and we do not sketch here.

4.2 Ultraproduct property for i-models

In this subsection we deal with the ultraproduct property for the class of i-models: for every non-empty family $\{\mathbf{A}_i\}_{i \in I}$ of i-webs and every ultrafilter U on $\mathcal{P}(I)$ the ultraproduct $(\prod_{i \in I} \mathbf{A}_i^+)/U$ can be embedded into an i-model.

Let J be a non-empty set and let $\{\mathcal{A}_j\}_{j \in J}$ be a family of information systems and let U be a proper ultrafilter on $\mathcal{P}(J)$. Define a binary relation θ_U on $\prod_{j \in J} A_j$ by setting $(\alpha, \beta) \in \theta_U \Leftrightarrow \{j \in J : \alpha(j) = \beta(j)\} \in U$.

Note that θ_U is an equivalence relation on $\prod_{j \in J} A_j$. As a matter of notation, for every finite subset $a \subseteq_f \prod_{j \in J} A_j$, we let $a/\theta_U = \{\alpha/\theta_U : \alpha \in a\}$, i.e., a/θ_U is the finite subset of $(\prod_{j \in J} A_j)/\theta_U$ constituted by the θ_U -equivalence classes of the tokens of a . Since each element $\alpha \in a$ is a J -indexed sequence, we denote by $\alpha(j)$ the j -th projection of α and we let $a(j) = \{\alpha(j) : \alpha \in a\}$.

Definition 4.3. We define an information system $\mathcal{P}_U = (P_U, \text{Con}_U, \vdash_U, v_U)$ as follows:

$$\begin{aligned} P_U &= (\prod_{j \in J} A_j)/\theta_U \\ v_U &= (\lambda j. v_{A_j})/\theta_U \\ a/\theta_U \in \text{Con}_U &\quad \text{iff} \quad \{j \in J : a(j) \in \text{Con}_{A_j}\} \in U \\ a/\theta_U \vdash_U \alpha/\theta_U &\quad \text{iff} \quad \{j \in J : a(j) \vdash_{A_j} \alpha(j)\} \in U \end{aligned}$$

We also define an i-web $\mathbf{P}_U = (\mathcal{P}_U, \phi_{P_U})$ by setting $\phi_{P_U}(a/\theta_U, \alpha/\theta_U) = (\lambda j. \phi_{A_j}(a(j), \alpha(j)))/\theta_U$.

We leave to the reader the easy verification of the fact that \mathcal{P}_U and \mathbf{P}_U indeed are an information system and an i-web, respectively.

We conclude the second main theorem of the section, the one that deals with the ultraproduct property. Let $\{\mathbf{A}_j\}_{j \in J}$ be a family of i-webs, let U be an ultrafilter over $\mathcal{P}(J)$ and let \mathbf{P}_U be the i-web of Definition 4.3. Since \mathbf{P}_U is an i-web, then \mathbf{P}_U^+ is a reflexive Scott domain and hence a λ -model. On the other hand each i-web \mathbf{A}_j gives rise to a reflexive Scott domain \mathbf{A}_j^+ , which is a λ -model. Then $(\prod_{j \in J} \mathbf{A}_j^+)/U$ is an ultraproduct of λ -models, and thus again a λ -model.

Theorem 4.5. There exists an embedding of combinatory algebras from the λ -model $(\prod_{j \in J} \mathbf{A}_j^+)/U$ into the λ -model \mathbf{P}_U^+ .

The proof of Theorem 4.5 is rather technical and cumbersome. For this reason we state and prove a particular case of Theorem 4.5 that only deals with graph models; the proof will appear clear and readable, and at the same time gives the core idea about the proof of the more general result.

Theorem 4.6. *There exists an embedding of combinatory algebras from the λ -model $(\prod_{j \in J} \mathbf{A}_j^+)/U$ into the λ -model \mathbf{P}_U^+ .*

Proof. We let x, y, \dots range over elements of $\prod_{j \in J} \mathbf{A}_j^+$, so that $x(j) \in \mathbf{A}_j^+$ is a point of the graph model \mathbf{A}_j . We write x/U for the equivalence class of x w.r.t. the congruence on $\prod_{j \in J} \mathbf{A}_j^+$ given by $x \sim_U y \Leftrightarrow \{j \in J : x(j) = y(j)\} \in U$, i.e., $x/U = \{y \in \prod_{j \in J} \mathbf{A}_j^+ : x \sim_U y\}$.

Recall that θ_U is the relation on $\prod_{j \in J} \mathbf{A}_j$ given by $(\alpha, \beta) \in \theta_U \Leftrightarrow \{j \in J : \alpha(j) = \beta(j)\} \in U$. We define a map $f : (\prod_{j \in J} \mathbf{A}_j^+)/U \rightarrow \mathbf{P}_U^+$ as follows:

$$f(x/U) = \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \forall j \in J. \alpha(j) \in x(j)\}$$

It is easy to show that the definition of f is independent of the choice of the representatives of \sim_U -equivalence classes as, for all $y \in x/U$, we have $\{j \in J : y(j) = x(j)\} \in U$.

We prove that f is injective. Suppose $x/U \neq y/U$ and let $Z = \{j \in J : x(j) = y(j)\}$. Define $X = \{k \in J : x(k) \subseteq y(k)\}$ and $Y = \{k \in J : y(k) \subseteq x(k)\}$. Then $X \cap Y = Z \notin U$. This means that it is not possible that both X and Y belong to the ultrafilter U . Assume that $X \notin U$. Then for every $k \in J - X$ we have $x(k) \not\subseteq y(k)$, so that for each $k \in J - X$ there exists an element $\gamma_k \in A_k$ such that $\gamma_k \in x(k) - y(k)$. Let $\delta \in \prod_{j \in J} A_j$ be an arbitrary sequence and let $\beta \in \prod_{j \in J} A_j$ be defined by $\beta(i) = \gamma_i$ for $i \in J - X$ and $\beta(i) = \delta(i)$ for $i \notin J - X$. By definition of f we have $\beta/\theta_U \in f(x/U)$, while $\beta/\theta_U \notin f(y/U)$, so that $f(x/U) \neq f(y/U)$.

Now we prove that f is homomorphism of combinatory algebras. We start proving that f preserves application. We have

$$\begin{aligned} f(x/U) \cdot f(y/U) &= \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \exists a/\theta_U \subseteq_f f(y/U). \phi_{P_U}(a/\theta_U, \alpha/\theta_U) \in f(x/U)\} \\ &= \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \exists a \subseteq_f \prod_{j \in J} \mathbf{A}_j. \forall \gamma \in a. \forall j \in J. \gamma(j) \in y(j) \wedge \forall i \in J. \phi_{A_i}(a(i), \alpha(i)) \in x(i)\} \\ &= \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \forall j \in J. \exists a \subseteq_f y(j). \phi_{A_j}(a, \alpha(j)) \in x(j)\} \\ &= \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \forall j \in J. \alpha(j) \in \{\beta \in A_j : \exists a \subseteq_f y(j). \phi_{A_j}(a, \beta) \in x(j)\}\} \\ &= \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \forall j \in J. \alpha(j) \in x(j) \cdot y(j)\} \\ &= f((x \cdot y)/U) \\ &= f(x/U \cdot y/U) \end{aligned}$$

We now regard the basic combinators. Recall that by definition for each $j \in J$ we have $\mathbf{k}^{\mathbf{A}_j^+} = \llbracket \lambda xy. x \rrbracket^{\mathbf{A}_j^+} = \{\phi_{A_j}(a, \phi_{A_j}(b, \beta)) : \beta \in a\}$. Then

$$\begin{aligned} f(\mathbf{k}^{(\prod_{j \in J} \mathbf{A}_j^+)/U}) &= f((\mathbf{k}^{\prod_{j \in J} \mathbf{A}_j^+})/U) \\ &= \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \forall j \in J. \alpha(j) \in \mathbf{k}^{\mathbf{A}_j^+}\} \\ &= \{\phi_{P_U}(a/\theta_U, \phi_{P_U}(b/\theta_U, \beta/\theta_U)) : \beta/\theta_U \in a/\theta_U\} \\ &= \llbracket \lambda xy. x \rrbracket^{\mathbf{P}_U^+} \\ &= \mathbf{k}^{\mathbf{P}_U^+} \end{aligned}$$

Similarly $f(\mathbf{s}^{(\prod_{j \in J} \mathbf{A}_j^+)/U}) = \mathbf{s}^{\mathbf{P}_U^+}$. □

We remark that in the general case in which all the \mathbf{A}_j ($j \in J$) and \mathbf{P}_U are i-webs the map $f : (\prod_{j \in J} \mathbf{A}_j^+)/U \rightarrow \mathbf{P}_U^+$ is defined as $f(x/U) = \{\alpha/\theta_U : \alpha \in \prod_{j \in J} \mathbf{A}_j, \forall j \in J. \alpha(j) \in x(j)\} \downarrow_{P_U}$.

We commented at the end of §4.2 that the fip can be derived for subclasses by suitably modifying the general construction detailed for i-models. Also the up holds for the various classes of models. Here

we proved it for graph models, because it looks very clear for this case, but the proof can be adapted (adding details and complication) to the other cases.

Summing up, graph models, pcs-models, Krivine models, filter models and in general i-models have both the fip and the upp. For this reason Theorem 3.1 applies to all these classes, producing a minimal model in each case. It is known that there exist filter-easy terms [1] as well as graph-easy terms [2] (for example $(\lambda x.xx)(\lambda x.xx)$), and every graph-easy term is also pcs-easy and Krivine-easy, since the latter classes contain the graph models. Therefore Theorem 3.3 and Theorem 3.4 both hold for all these classes, saying that each one of them induces a continuum of lambda-theories.

5 Conclusions

We have presented a method for proving that a given class of models of the λ -calculus possesses a minimal element, *i.e.* an element whose λ -theory is the intersection of all the λ -theories represented in the class.

Then, we have applied this method to the class of i-models, a subclass of Scott models defined in [10], containing several well-known instances of “webbed” models like the graph-models and the filter models living in the category of Scott domains.

Various extensions of this work can be explored, both toward the proof that the whole class of Scott models has the minimality property, and more generally toward the application of the method to other classes of models of the λ -calculus.

Concerning the former extension, a preliminary result would be the finite intersection property for the whole class of Scott models, the completion method described in section 4 being adapted to i-models.

More generally, it is interesting to notice that webs, even beyond i-webs, are first-order axiomatisable, hence closed by ultraproducts (by the way, this observation is an alternative way of showing that Definition 4.3 is sound).

By providing a first-order axiomatisation of sentences like $\mathbf{A}^+ \Vdash M \neq N$, for given terms M, N and web \mathbf{A} , we could invoke Los theorem for showing that $(\prod_{j \in J} \mathbf{A}_j) / \theta_U$ and $(\prod_{j \in J} \mathbf{A}_j^+) / U$ have the same theory, and hence for deriving a strong form of the ultraproduct property for the class of models corresponding to the considered webs.
